Use Case Implemented:

1. **Use Case I**: User Login/Sign Up (Become A Member)

Progress: 90%

The web app has the login page and sign up page. The login page is not functional for the moment [no backend yet]. The sign up page is 80% functional which means that the user's information once inserted into the form, will be inserted into the database. The only missing features of the sign up page is the errors displaying on the form. For example: invalid email address, invalid username, etc… But the backend for errors is already implemented.

Updates: Errors have been implemented successfully. Signup and login page are working successfully. The user now can login into the page and the session will start for that specific user.

2. Use Case II: Contact Us/Support Us Form

Progress: 100%

The user can send a message with a specific subject to the databases. Error handling has been implemented as well to avoid users sending invalid queries or empty messages to the databases.

3. Use Case III: Subscribing to newsletters

Progress: 100%

The user can subscribe to the newsletters by entering their email address to the small form within the footer. Error handling has also being implemented to avoid user sending empty query to the database.
